General Note: You may give all answers directly on these pages. If you remove the staples please add your name and matriculation number on **each** page. Overall you can reach 50 points in part 1 and 50 points in part 2.

Examination Question 1 "Advanced Testing" (10 Points)

Given is the following class under test. The class creates and opens a Swing-window with a button on it. The supplied ActionListener contains a (possible) complex interaction logic. For solving the Questions it is not necessary to understand this code fully.

```
import java.awt.Dimension;
import java.awt.event.ActionListener;
import javax.swing.JButton;
import javax.swing.JFrame;
import javax.swing.JPanel;
public class GUI extends JFrame {
     public GUI(ActionListener al){
          super("Sample");
          JButton b = new JButton("Press");
          b.addActionListener(al);
          JPanel p = new JPanel();
          p.add(b);
          this.setContentPane(p);
          this.setPreferredSize(new Dimension(200, 300));
          this.setDefaultCloseOperation(EXIT_ON_CLOSE);
          this.setLocationByPlatform(true);
          this.pack();
          this.setVisible(true);
     }
```

| Fach: | Software Engineering 2 (Part 2) | Matrikel-Nr.: |

For testing the above class a **test double** is crreated which implements the interface ActionListener. An ActionEvent contains several details about an action triggered (e.g. the originater of the action, which would be the pressed button in this example). Again, For solving the questions it is not necessary to understand ActionEvents. The test double is implemented the following way:

```
import java.awt.event.*;
import java.util.*;

public class TestListener implements ActionListener {
    List<ActionEvent> events = new ArrayList<>();

    public List<ActionEvent> getEvents() {
        return events;
    }

    @Override
    public void actionPerformed(ActionEvent event) {
        events.add(event);
    }
}
```

The above test double is used in the context below.

```
public class TestGUI {
    private static GUI gui;
    private static TestListener listener;

    @BeforeClass
    public static void setUp(){
        Listener = new TestListener();
        gui = new GUI(listener);
    }
    @Test
    public void test(){
        // run some tests on gui here
        List<ActionEvent> events = listener.getEvents();
        // assert that some events happened here
    }
}
```

Java-Reflection, mockito, and AspectJ all provide means to access or change otherwise inaccessible or intangible parts of a java program. For each of these technologies give one sample use case, for what it could be used.

Examination Question 2 "Design Patterns" (10 Points)

With the help of the composite pattern the following task should be solved:

For a drawing program shapes should be organized. Shapes should be either primitive shapes like Circle or Rectangle or a group of shapes. Groups may contain (an unlimited number of) either primitive shapes or again groups. A method count():int should return the number of primitive shapes contained within one shape. This method should be available for all shapes.

| should be available for all shapes. |

Examination Question 3 "Metrics" (10 Points)

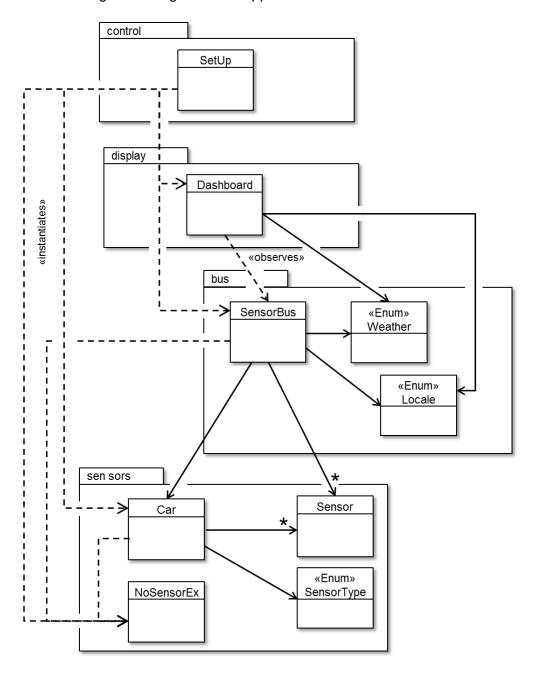

Given are the definitions of the following two Martin-Metrics (as discussed in the lecture)

Afferent Couplings (CA_p) of a package p: the number of classes **outside** of this package that depend upon classes within this package.

| Efferent Couplings (CE_p) of a package p: the number of classes inside this package that depend upon classes outside of the package. | | | | |
|--|--|--|--|--|
| · · · · · · · · · · · · · · · · · · · | | | | |
| What does the afferent coupling of a package indicate – i.e. what does it want to measure? | | | | |
| | | | | |
| What does the efferent coupling of a package indicate – i.e. what does it want to measure? | | | | |
| As discussed in the lecture – metrics are models too. According the lecture, describe what is modeled here; i.e. what element model? | | | | |
